Supplementary Figure 1 | Static and dynamic map of RNA polymerase binding.

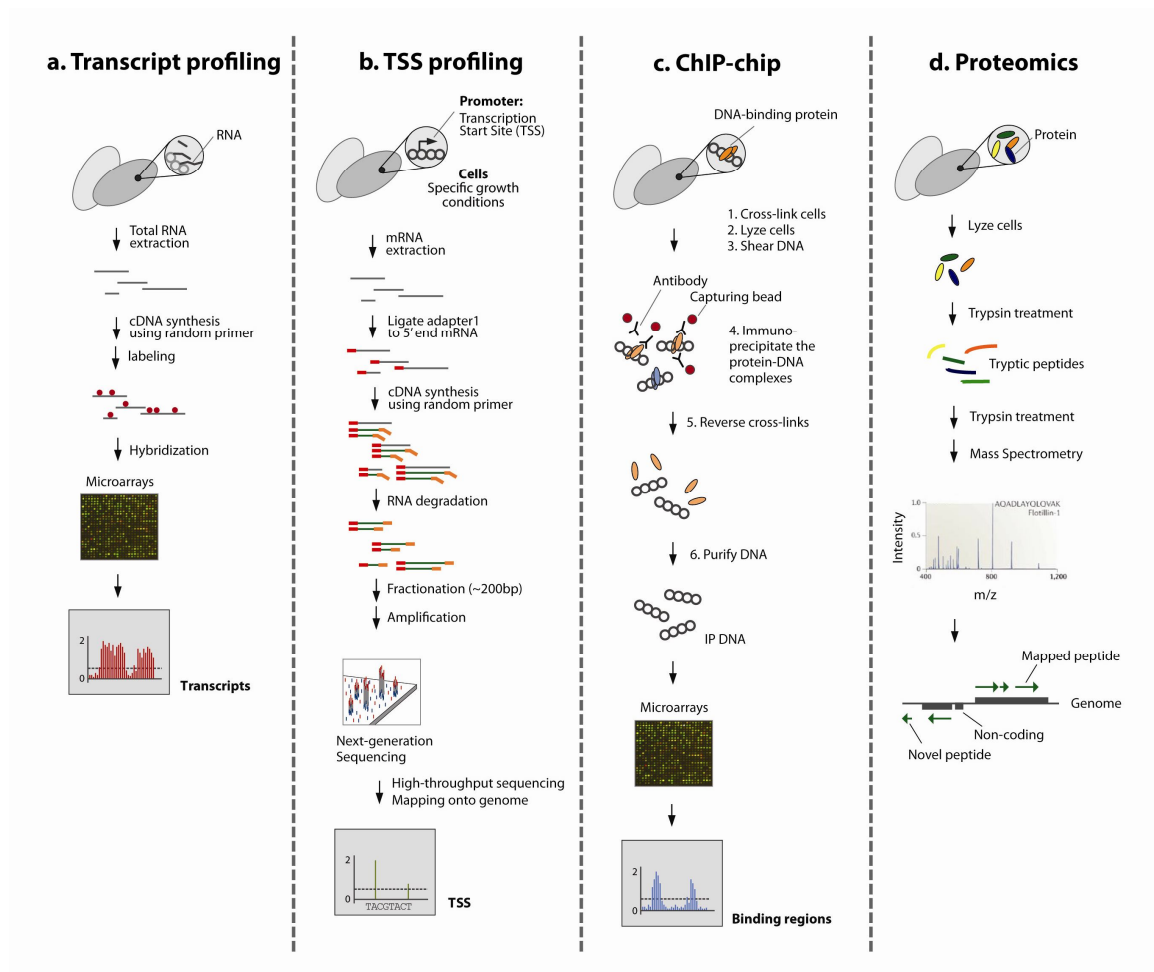

Determination of the binding locations of RNA polymerase was nearly condition dependent. Although we observed the differential binding levels of RNA polymerase under different conditions, the binding locations (i.e., promoter regions) were nearly identical. **(a, b)** Examples of RNA polymerase (RNAP) binding under different growth conditions (log phase, red; heat-shocked, grey; stationary phase, orange). Binding of RNAP was determined by the static map although regions of log phase cells or log phase and heat-shocked cells did not show RNAP binding under the dynamic map. Regions of differential binding are highlighted in red. **(c)** Static RNAP-binding maps of log phase (red) and leucine condition (blue). We observed differential RNAP-binding levels, however, the binding locations of RNAP was nearly identical.

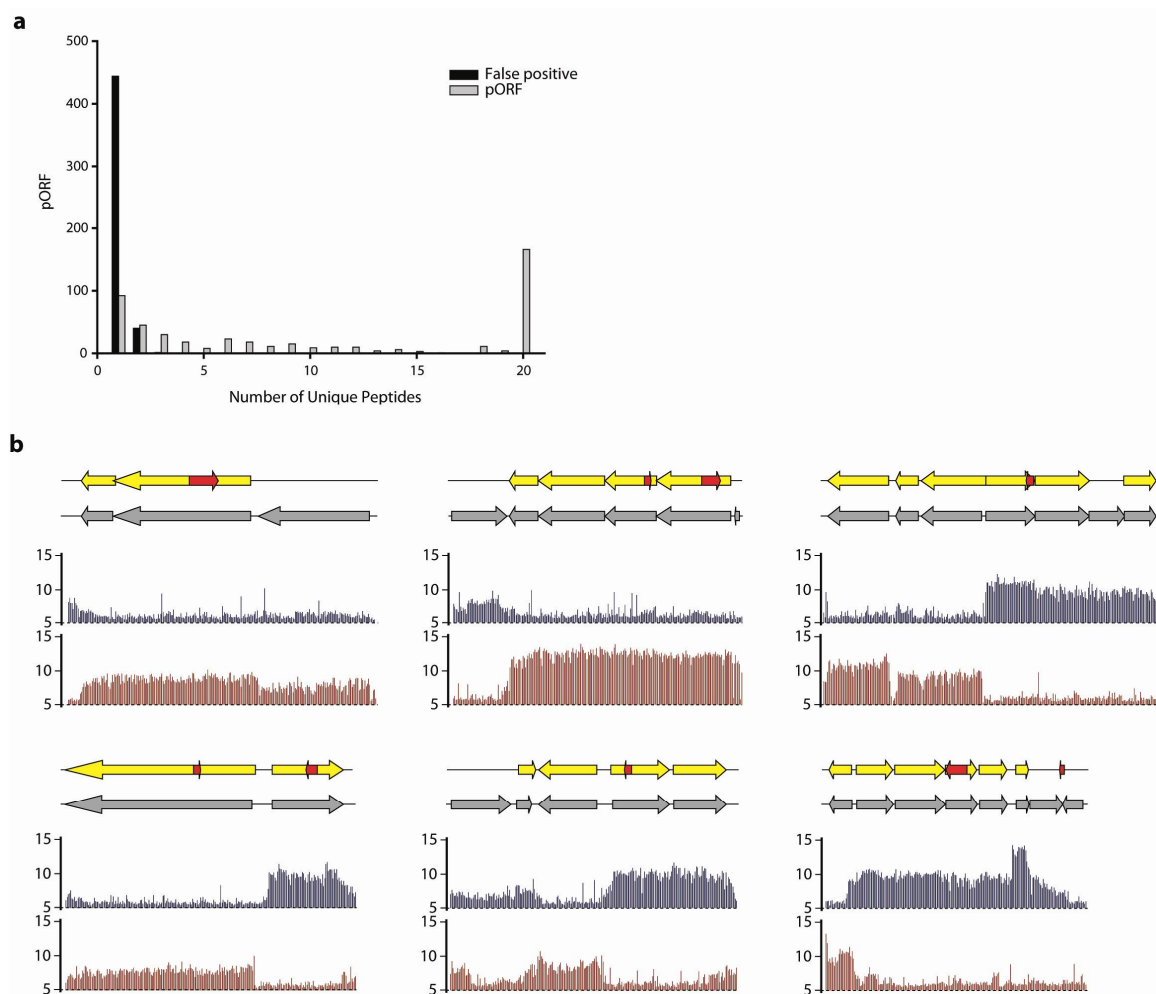

Supplementary Figure 2 | Comparison of RNAP-guided transcript segment (RTS) to change point algorithm and running-window approach. Integration of RNA polymerase binding regions (RBRs) with binary transcript calls (BT) lead to RTSs. RTS, based on integration of two experimental derived genome-wide data sets, yielded the best results when compared to change point algorithm (CP) and running window approach (RW). Two examples (**a**, **b**), representative for all data, demonstrate that determination of transcription fragments using CP resulted in too many fragments (too sensitive), whereas the RW yielded too few fragments (less sensitive).

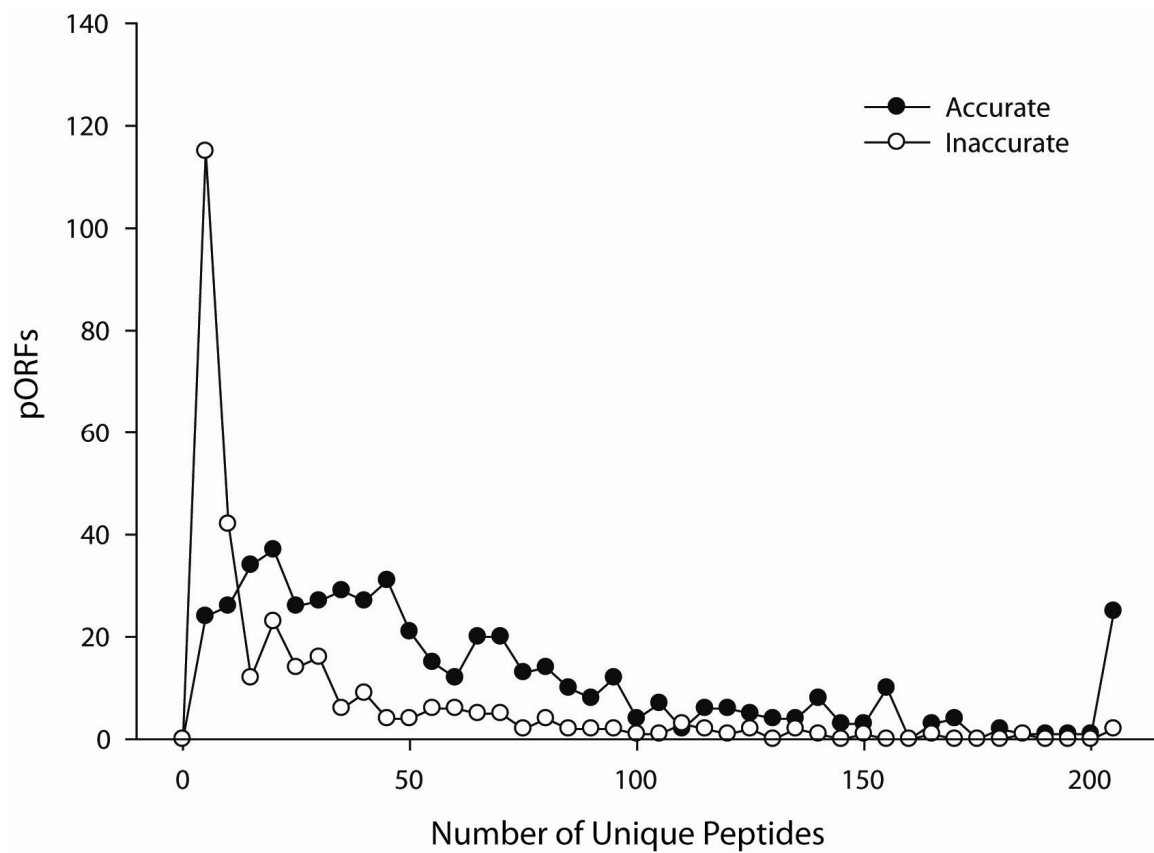

Supplementary Figure 3 | Increase of genomic coverage and accuracy by iterative integration. Iterative integration of transcripts, derived from various growth conditions, with RNA polymerase binding regions (RBRs) resulted in increased genomic coverage and accuracy (**a**, **b**, **c**), genes of interest are highlighted in red. Iteration of data from various growth conditions (log phase, red; heat-shocked, blue; stationary phase, orange) also allowed for determination of condition-specific transcripts, such as *yjcC* (**b**) and *ybaE* (**c**) from stationary growth phase, and *soxR* (**b**) from heat-shocked cells.

Supplementary Figure 5 | Flowcharts of the molecular biology tool box for the elucidation of the organizational components. Various genome-scale methods were deployed and developed to determine the meta-structure. Methods are depicted here include **(a)** transcription profiling, **(b)** transcription start site (TSS) profiling, **(c)** chromatin immunoprecipitation coupled to microarrays (CHIP-chip), and **(d)** proteomics.

Supplementary Figure 6 | Overlapping pORFs. (a) Frequency of peptide detection in the region where overlapped pORFs were found, (b) Examination of translation directionality of the overlapped pORFs based on the mRNA transcript profiles. The red arrows indicate false positives that were detected as pORFs.

Supplementary Figure 7 | Number of unique peptides from pORFs with accurate and inaccurate boundaries. Among 803 pORFs mapped to the validated ORFs (from EcoGene), a total of 507 pORFs showed accurate translation start/stop positions (filled circle). pORFs with non-matching translation start positions (296 pORFs) exhibited poor peptide coverage (open circle). Due to this coverage limitation, additional methods (e.g., proteomics with N-terminal modification) have to be applied to obtain a more comprehensive and accurate ORF map at a genome-scale.

Supplementary Figure 8 | Use of alternative TSSs. (a) The *serA* gene, *serC-aroA* operon, and *gltBDF* operon have multiple experimentally verified TSSs. We detected the dominant TSS (3,056,478) for the *serA* promoter, which is highly activated by the transcription factor Lrp. Another experimentally confirmed TSS (3,056,571) is likely to be utilized less under this growth condition. The transcription factor Lrp also activates one experimentally verified TSS (956,818) of the *serC* promoter, which was detected as a

dominant TSS in this study. In addition, we found another TSS (956,802) at the *serC* promoter. The other previously confirmed TSS (3,352,531) at the *glbB* promoter was detected as a dominant TSS with Lrp-binding signal. **(b)** List of TSSs regulated by the transcription factor Lrp. We observed the alternative TSSs at the various promoter regions regulated by Lrp.

Supplementary Figure 9 | 5'UTR length of various functional categories. (a) Distribution of 5'UTR shows a median length maximum of ~36 bp, **(b)** comparison of 5'UTR length (in base pairs) showed no difference between different functional categories.

Supplementary Table 1: Genome-scale determination of RNA polymerase binding regions (RBRs). "Static" and "Dynamic" indicate RNA polymerase ChIP-chip experiments with rifampicin treatment and without treatment, respectively. Each value in column 3-7 indicates binding levels (\log_2 ratio) of RNA polymerase under log phase (log), heat-shocked (heat), stationary phase (stat), and glutamine (gln) growth conditions.

Supplementary Table 2: Iterative analysis of expression profiles. "Total probes" indicates total number of probes within ORF region. "Expressed probes" was determined by transcriptiondetector algorithm. "Probe density (%)" shows the ratio between the expressed probe and total probes within ORF region. Abbreviations: R1, log phase; R2, log phase+heat-shocked condition; R3, log phase+heat-shocked condition+stationary phase; R4, log phase+heat-shocked condition+stationary phase+glutamine growth condition; P, presence; A, absence; U, uncharacterized gene.

bnum	Gene	start	end	direction	size	total probes	Expressed probes				Probe density (%)				presence/absence call				Note

Supplementary Table 6: Genome-scale proteomics data obtained from log phase, heat-shocked, stationary phase growth conditions (this study), and publicly available source. Abbreviations: PLOG, peptide ID for log phase; PHEAT, peptide ID for heat-shocked condition; PSTAT, peptide ID for stationary phase; PPUB, peptide ID for publicly available source; FOC, filtered observation count; Length, peptide length.
