Appendix A1: Comparison between OECD-ABC Signatories and Non-Signatories in 2010.

This table presents a balance test at the country-level. It demonstrates that signatories of the OECD-ABC convention were structurally different on a number of important characteristics from non-signatory countries represented in the PCI dataset in the first year of Phase 3 of the Convention. As a result, any analysis which strictly looks at the cross-sectional relationship between OECD-ABC status and outcomes would be potentially biased. Consequently, we use a diff-in-diff design to illustrate the change in firm behavior over time.

Potential Confounders	Mean		Standard Deviation		Differences	
	OECD	Non-OECD	Treatment	Control	p-value	t-test
All Countries in Dataset 2005-2015 (n=296)

All data in balance test from Teorell, Jan, Stefan Dahlberg, Sören Holmberg, Bo Rothstein, Anna Khomenko & Richard Svensson. 2017. The Quality of Government Standard Dataset, version Jan17. University of Gothenburg: The Quality of Government Institute, <http://www.qog.pol.gu.se> doi:10.18157/GoGStdJan17

Appendix A2: Dynamic Balance Test

This table extends on the balance test above. Here, we study firm-level characteristics among OECD-ABC signatories and non-signatories. The analysis uses the full PCI dataset in the following equation ($y_{it} = \beta_0 + \beta_1 OECD + \beta_2 Phase3 + \beta_3 OECD * Phase3 + \lambda + e_{it}$). Each row represents the regression of the variable in the first column (y) on the interaction of OECD and Phase 3 including survey year fixed effects. i is an index of firms and t indexes the year they completed registration activities. We also include a set of survey year effects (λ). The third column lists β_3 , which is the diff-in-diff coefficient. The trends in sectors at the two-digit ISIC level is depicted in Figure A2.1 below.

Potential Confounders	Firm Entered Vietnam before Phase 3		Firm is from OECD Signatory Country		Interaction between Phase3 and OECD		Constant		n	R-squared
	Coefficient	95% CI	Coefficient	95% CI	Coefficient	95% CI	Coefficient	95% CI

A6. Test of Floor and Ceiling Effects

(Change in Non-Sensitive Activities among Firms from OECD Signatories)

Bribery at Entry

Before Phase 3

After Phase 3

Appendix 7: Robustness Tests for Diff-and Diff Estimator

At first blush, the findings appear compelling, but the timing of Phase 3, the type of corruption measured, and the implementation of the PCI survey pose a number of threats to inference. In this Appendix, we tackle these threats one by one: 1) the parallel trends assumption; 2) bandwidth size; and 3) earlier entry years.

A7.1. Parallel Trends Assumption

The diff-in-diff estimator identifies the impact of the treatment under the parallel trends assumption that the unobserved difference between the treatment and control groups is time-constant before the intervention. In non-statistical jargon, our findings could be biased if corruption among signatory firms was already in decline prior to Phase 3 because of lagged responses to earlier OECD-ABC phases, regulatory responses to the sub-prime financial crisis, or Vietnam's entry into more restrictive international economic agreements, such as the U.S. Bilateral Trade Agreement in 2000 or the WTO in 2007.

To address these concerns, we run a series of placebo tests that re-run our preferred specification (Table 2, Model 5) but vary the cut-off year for the before and after analysis. If prior declines in OECD-ABC corruption are really responsible for our finding, the interaction term should be significant for those other years as well. The top panel of Figure A7.1 plots the results of 16 regressions for each year (y) between 1997 and 2016, where "after" is defined by entry years greater than the y ($\text{after} = 1$ if $\text{entry year} > y$; 0 otherwise). For each year, we depict the coefficient on the OECD*Year interaction term surrounded by a 95% confidence interval.

Notice that the key interaction term for every year between 1997 and 2008 is not robustly significant across specifications, and more importantly, has the wrong sign in most models. With the exception of 2001, we do not observe a significantly negative coefficient until entry years greater than 2009, the actual Phase 3 cut-off year. That is, the predominant trend prior to Phase 3 was that changes in corruption among OECD-ABC signatory firms was roughly equivalent to their non-signatory peers.¹ In sum: 1) there is no evidence that

OECD-ABC countries were generally less corrupt prior to Phase 3, and 2) violations of the parallel trends assumption cannot be responsible for the change in behavior we observe. Thus, there is no evidence that alternative factors, occurring prior to 2010, are responsible for the effects we observe in Table 2.

This trend can also be observed in Figure A7.2, where we calculate the average bribe propensity every five years going back to 1989. Notice that firms from signatories and non-signatories bribe at very similar levels until they hit the red line denoting the Phase 3 onset after 2009.

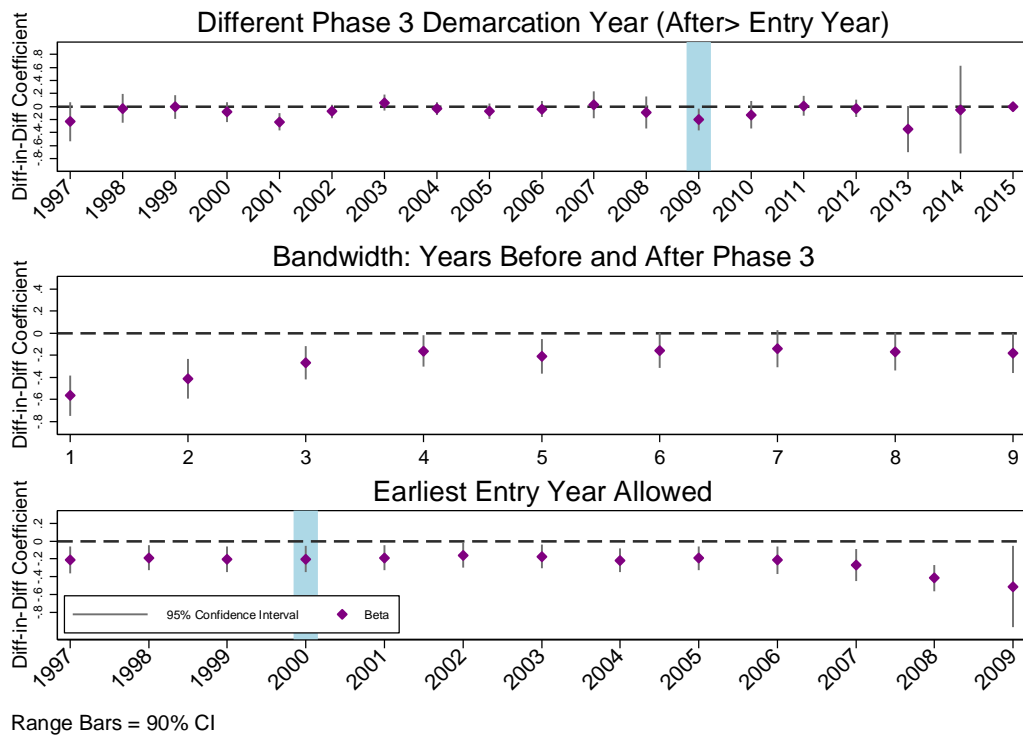

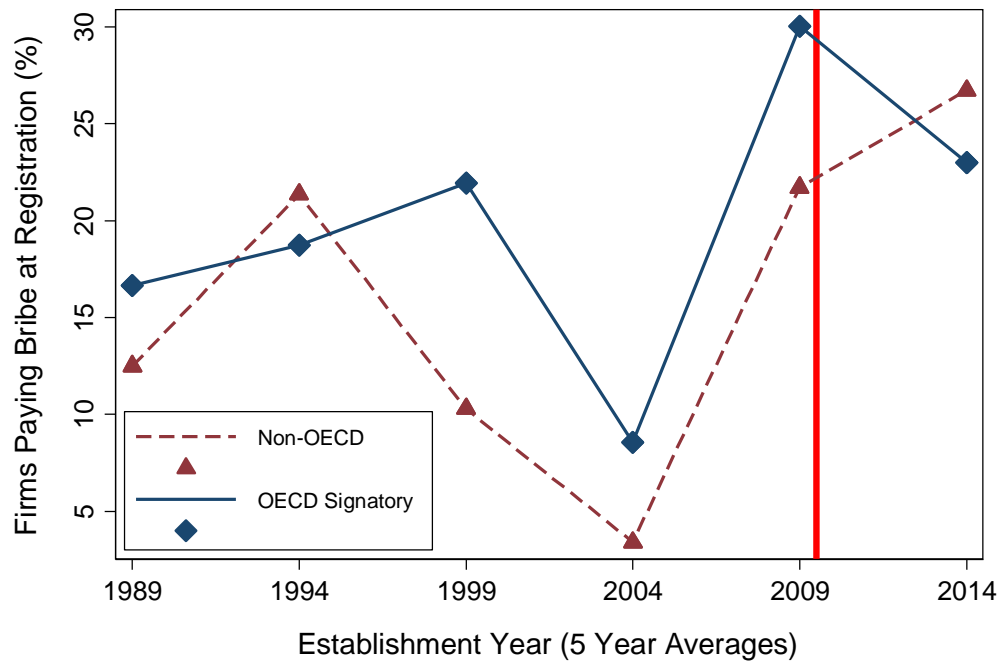

Figure A7.1: Robustness Tests. The top panel demonstrates a test of the parallel trends assumption by re-running the same analysis as Table 2 (Model 6), but replacing the year defined as the onset of Phase 3 with a range of different years. The light blue shade shows the cut-off year actually used in the main analysis. The bottom panel tests different bandwidths around the 2009 cut-off, ranging from 1 to 9 years. Range bars represent 90% Confidence Intervals.

Bar denotes start of OECD-ACB Phase 3 after December, 2009

Appendix A7.1: Graphical Display of Parallel Trends Assumption: Looks at average bribery over five-year periods among signatories and non-signatories of OECD countries. The red line at 2009 indicates the onset of Phase 3.

Appendix 7.2: Varying Bandwidth

A second concern with our analysis is that our relatively open window on both sides of Phase 3 is allowing for the capture of behavior that takes place significantly after the beginning of 2010. For instance, if firms from OECD-ABC signatory countries coincidentally enter less corruption-prone sectors or use less corruption-prone entry procedures after 2014, then by averaging together all bribery after the beginning of 2010, we might be conflating these structural changes in the Vietnamese and global economy with responses to the Convention.²

On the other side of the coin, our decision to include the responses of all firms that registered after 2005 in the analysis may introduce recall bias; specifically, this recall bias could occur because we are comparing firms that registered long ago and that may have developed negative memories of the registration period with those that registered more recently and have not had time to let their experiences in Vietnam potentially cloud their memories. To make sure our results survive this form of bias, we re-run the analysis allowing windows

² Online Appendix 2 shows that there is little evidence for such structural change within our sample of firms on observable indicators, especially sector (See Figure A2.1), but bias on unobservables is also possible.

around the cut-off to vary from the narrow one year since registration (only firms in 2009 and 2010) to the less narrow nine years.³ These results can be seen in the bottom panel of Figure A7.1.⁴

Importantly, the choice of bandwidth has very little impact on the estimated reduction in corruption. Although the model's efficiency decreases with very limited windows because of the smaller number of respondents, the overall diff-in-diff coefficient is consistently around 40 percentage points. In fact, the one-year bandwidth actually indicates the sharpest decline among OECD-ABC signatories—roughly 60 percentage points.

Appendix 7.3: Earlier Entry Years

In the main estimation, we dropped all FIEs which entered after 2005, because we worried about recall bias. In the third panel of Figure A7.1, we run Model 5 (Table 2), but vary the initial year below which we drop firms. As can be seen, the choice of entry year makes no difference in the analysis.

³ The last observed registration year is 2014, not 2015 in that analysis.

⁴ A separate robustness test in Online Appendix 12 also experiments with including the earliest entry year allowed to check the impact of recall bias on results. Again, results are all significant and similarly signed.

Appendix A8: Home Country Enforcement and Procurement

Table 5: Heterogeneous Impact of Home Country Enforcement on Corruption During Procurement

<i>Dependent variable: difference between the activities reported by treatment group and predicted number of nonsensitive activities of control group.</i>	All Firms Registered after 2005
